

So to calculate how many fleets there are , we first sort the input array based on position
then we use a stack to put in it the cars
then traverse the array in reverse from the end and add the car to the stack since it's empty continue
then add another car to the stack , if the arrival time (calculated in constant time) of the car in the stack is smaller (earlier) than the one under it , then we pop it from the stack because now they are merged into one
and the number of car fleets is the size of the stack
